

# Solutions for Exercise Sheet 5

Handout: Oct 15th — Deadline: Oct 22nd, 4pm

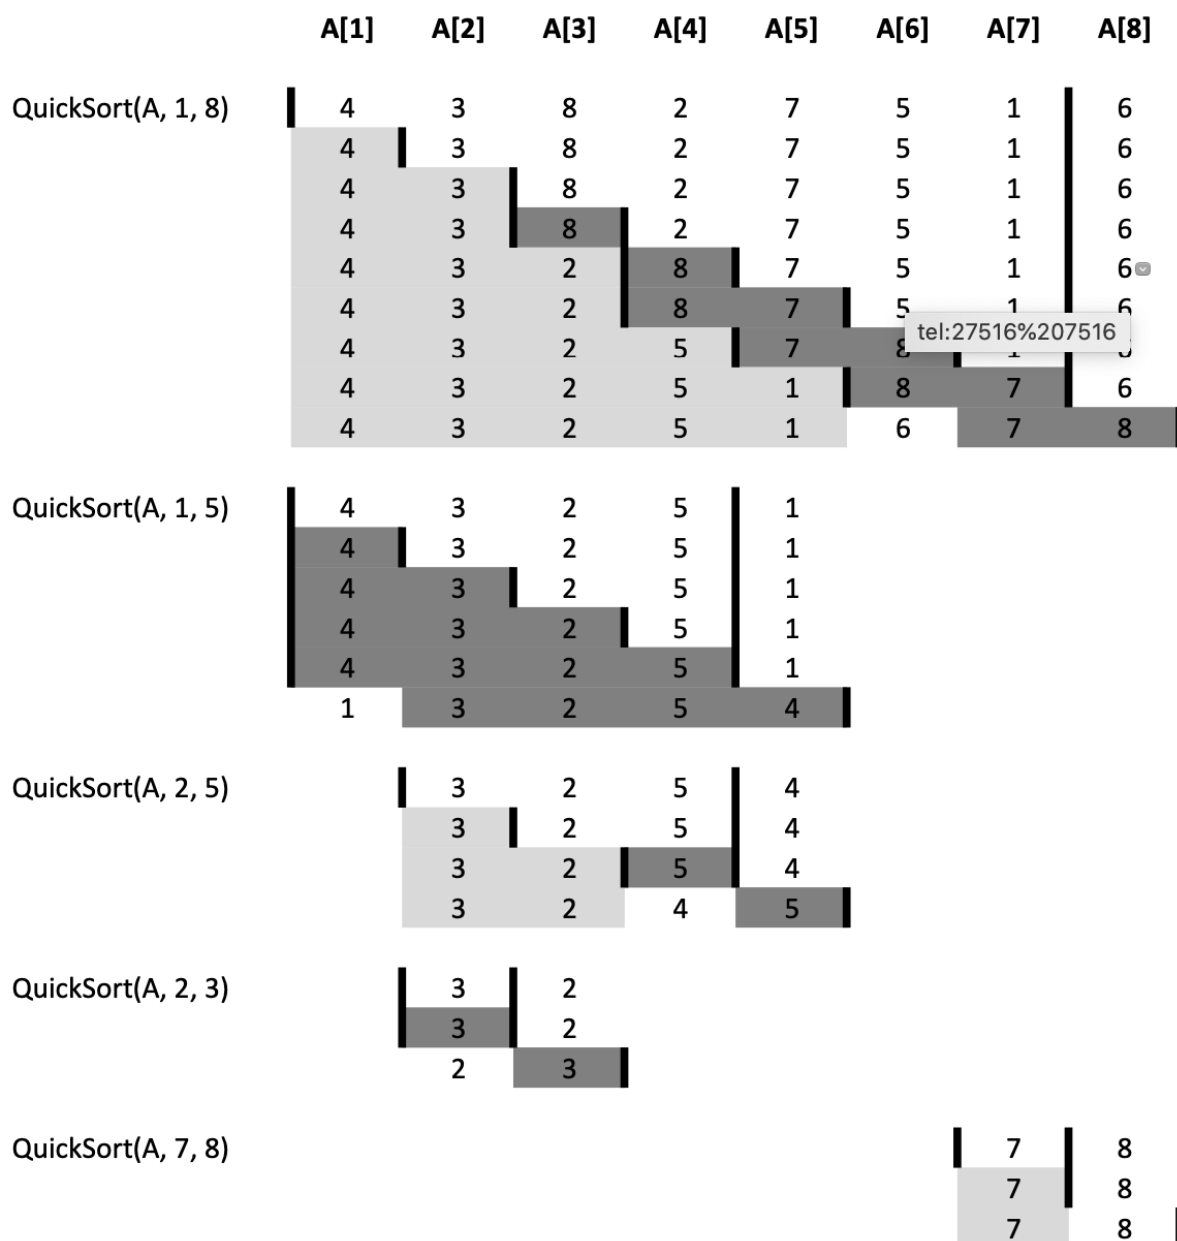

## Question 5.1 (Marks: 0.25)

Illustrate the operation of QUICKSORT on the array

4	3	8	2	7	5	1	6
---	---	---	---	---	---	---	---

Write down the arguments for each recursive call to QUICKSORT (e.g. “QUICKSORT( $A, 2, 5$ )”) and the contents of the relevant subarray in each step of PARTITION (see Figure 7.1). Use vertical bars as in Figure 7.1 to indicate regions of values “ $\leq x$ ” and “ $> x$ ”. You may leave out elements outside the relevant subarray and calls to QUICKSORT on subarrays of size 0 or 1.

**Solution:**

**Question 5.2** (Marks:0.5)

Prove that deterministic  $\text{QUICKSORT}(A, p, r)$  is correct (you can use that  $\text{PARTITION}$  is correct since that was proved at lecture).

**Solution:** We prove it by induction on the length of the array  $A$ .

**Base case:**  $n=1$

We have  $p \leq r$  and the algorithm returns the element untouched.

**Inductive case:** We assume the algorithm works for lengths up to  $n - 1$  and prove that it works for length  $n$ .

$\text{PARTITION}$  returns the array  $[p, \dots, q - 1, q, q + 1, \dots, r]$  where the elements before  $q$  are smaller than  $q$  and the elements after  $q$  are larger.

Then  $\text{QUICKSORT}[p, \dots, q - 1]$  and  $\text{QUICKSORT}[q, \dots, r]$  return the respective subarrays sorted by inductive hypothesis so the algorithm is correct as  $q$  is in the right place already.

**Question 5.3** (Marks: 0.25) What is the runtime of  $\text{QUICKSORT}$  when the array  $A$  contains distinct elements sorted in decreasing order? (Justify your answer)

**Solution:** Partition will always return either the largest or the smallest element. So we get the same recurrence equation as when the array is increasingly ordered:  $T(n) = T(n - 1) + \Theta(n)$  leading to a  $\Theta(n^2)$  runtime.

**Question 5.4** (Marks: 0.5)

What value of  $q$  does  $\text{PARTITION}$  return when all  $n$  elements have the same value?

What is the asymptotic runtime ( $\Theta$ -notation) of  $\text{QUICKSORT}$  for such an input? (Justify your answer).

**Solution:**  $\text{PARTITION}$  will include all equal elements in the left-hand part of the array, increasing  $i$  in every iteration of the loop. The loop will terminate with  $i + 1 = r$ , hence swapping the pivot with itself and returning  $q = r$ .

The runtime of  $\text{QUICKSORT}$  is  $\Theta(n^2)$  as the size of the larger subarray is only reduced by 1 in each recursive call. An input of  $n$  equal values is a worst-case input for  $\text{QUICKSORT}$ !

**Question 5.5** (Marks: 0.5)

Modify  $\text{PARTITION}$  so it divides the subarray in three parts from left to right:

- $A[p \dots i]$  contains elements smaller than  $x$
- $A[i + 1 \dots k]$  contains elements equal to  $x$  and
- $A[k + 1 \dots j - 1]$  contains elements larger than  $x$ .

Use pseudocode or your favourite programming language to write down your modified procedure **PARTITION'** and explain the idea(s) behind it. It should still run in  $\Theta(n)$  time for every  $n$ -element subarray. Give a brief argument as to why that is the case. **PARTITION'** should return two variables  $q, t$  such that  $A[q \dots t]$  contains all elements with the same value as the pivot (including the pivot itself).

Also write down a modified algorithm **QUICKSORT'** that uses **PARTITION'** and  $q, t$  in such a way that it recurses only on strictly smaller and strictly larger elements.

What is the asymptotic runtime of **QUICKSORT'** on the input from Question 5.4?

**Solution:** The idea behind the pseudocode given below is as follows. There are three cases for the new element  $A[j]$ . If it is larger than  $x$ , nothing needs to be done as  $A[j]$  is in the right place. If it is equal to  $x$ , we put it in the middle part by increasing  $k$  and swapping it with  $A[k]$ . If it is smaller than  $x$ , we need to shift the right and the middle parts by 1. This can be achieved by first swapping  $A[j]$  with  $A[k]$ , the last element of the middle part, and then swapping it again with the last element of the left part,  $A[i]$  (after increasing  $i$  and  $k$ ).

At the end, the pivot is swapped with  $A[k + 1]$ , the first element amongst those larger than the pivot.

There is only a constant number of swaps and other operations in each execution of the loop, so the runtime for an  $n$ -element subarray is still  $\Theta(n)$ .

---

**PARTITION'**( $A, p, r$ )

---

```

1:  $x = A[r]$ 
2:  $i = p - 1$ 
3:  $k = p - 1$ 
4: for  $j = p$  to  $r - 1$  do
5:     if  $A[j] = x$  then
6:          $k = k + 1$ 
7:         exchange  $A[k]$  with  $A[j]$ 
8:     if  $A[j] < x$  then
9:          $i = i + 1$ 
10:         $k = k + 1$ 
11:        exchange  $A[k]$  with  $A[j]$ 
12:        exchange  $A[k]$  with  $A[i]$ 
13: exchange  $A[k + 1]$  with  $A[r]$ 
14: return  $i + 1, k + 1$ 

```

---

The modified **QUICKSORT** algorithm then looks as follows:

---

**QUICKSORT'**( $A, p, r$ )

---

```

1: if  $p < r$  then
2:      $q, t = \text{PARTITION}'(A, p, r)$ 
3:     QUICKSORT'( $A, p, q - 1$ )
4:     QUICKSORT'( $A, t + 1, r$ )

```

---

The runtime of **QUICKSORT'** on an input of  $n$  equal elements is  $\Theta(n)$  (essentially the time for **PARTITION'**( $A, 1, n$ )) as **QUICKSORT'**( $A, 1, n$ ) leads to recursive calls on two empty subarrays.

**Question 5.6** (Marks:0.5)

Implement **QUICKSORT** and **QUICKSORT'** from Question 5.4
